

FLUORESCENT LAMP, METHOD FOR MANUFACTURING THE SAME,
AND FLUORESCENT LAMP DEVICE

BACKGROUND OF THE INVENTION

The present invention relates to a fluorescent lamp, a method for manufacturing the fluorescent lamp and a fluorescent lamp device and preferably, to a fluorescent lamp which can cope with its lamp life end in a high frequency operation. More particularly, the present invention relates to a fluorescent lamp which can suppress melting of stem glass when inner lead wires of a stem are discharged as electrodes and can prevent short-circuiting between the inner lead wires caused by adhesion or deposition of spattering material produced by vaporization of filaments and inner lead wires, a method for manufacturing the fluorescent lamp and a fluorescent lamp device.

When a high frequency power is applied between
15 counter electrodes of a fluorescent lamp to light the lamp,
a phenomenon unique to lamp life (the lamp reaches its life
end when the lamp has been operated for an accumulated time
of several thousands of hours) end takes place. When the
lamp comes to the end of the life and emitter material
20 coated on filaments disappears, the lamp usually cannot
come on and comes to its life end. However, even when the
emitter of the filaments becomes null, there may occur such
an unexpected situation that discharge is maintained with
the filaments having the emitter already disappeared or

inner lead wires being acting as hot spots. In this case, when discharge is maintained with, in particular, the inner lead wires acting as the hot spots, a discharge current larger than its rated value flows through the lead wires.

5 For this reason, the lead wires may melt and eventually its stem may be thermally melted, which operation is called a first operation mode.

Further, in another life end mode of the fluorescent lamp, the material (W) of the filaments, the emitter

10 material (BaO, etc.) coated on the filaments and the material (Ni, Fe) of the inner lead wires spatter and adhere or deposit onto tip end faces of flare stems close to the filaments. In particular, at the end of the lamp life, these substances tend to spatter and adhere or

15 deposit onto the tip end face of each of the flare stems.

The above adhesive or deposit, which is electrically conductive, may establish an electric path and energized when deposited. More specifically, the spattered material adhered and deposited on the tip end face of the flare stem 20 may establish an electric path on the surface of the flare stem between a pair of electrically-isolated inner lead wires, thus leading to electric conduction between the inner lead wires. In such a case, a current flows through the electric path to heat the flare stem surface, which 25 disadvantageously results in over-heat damage of the flare stem or in a large wattage loss due to short-circuiting. Such an operation mode is called a second operation mode.

The invention for overcoming the problem with the

second operation mode is disclosed in JP-A-6-338289 Publication (referred to as the known citation 1, herein-after), which will be briefly explained below.

Figs. 1A to 1C shows an embodiment of a lamp
5 disclosed in the known citation 1, wherein Fig. 1A is a cross-sectional view of the lamp, Fig. 1B is a cross-sectional view of the lamp taken along line A-A in Fig. 1A, and Fig. 1C is a cross-sectional view of the lamp taken along line B-B in Fig. 1A. As shown in Fig. 1B, a recess
10 202 is made in a flare stem at at least one of root parts of a pair of inner lead wires 201 (The recess is made only at one lead wire in the drawing). In Fig. 1C, reference numeral 203 denotes an exhaust hole of an exhaust tube in the flare stem. Also disclosed in the citation 1 is that
15 the recess may be made in an intermediate part 204 of the flare stem. Such a recess functions as a drop place. With such an arrangement, at the end of the lamp life, substance spattered from the electrode deposits on the flare stem. However, there is such a description in the citation that
20 the presence of the recess functioning as the drop place makes it difficult for the substance to deposit only on that recess area, thus preventing establishment of an electric path and avoiding an electric short-circuiting between the pair of lead wires.

25 Fig. 2 is an alternate of the arrangement of Fig. 1 disclosed in the citation 1. In the drawing, the same reference numerals as those in Fig. 1 denote the same parts. The arrangement of Fig. 2 is different from that of

Fig. 1 in that the recess 202 is replaced by such an insulation tube 205 as to surround the neighborhood of a sealing part of at least one of the inner lead wires 201 (The insulation tube 205 is provided only one lead wire in 5 the drawing). With such an arrangement, the above spattered substance can deposit on the flare stem but less deposit on the inner lead wires 201 in the vicinity of the sealing part, thus blocking formation of the aforementioned electric path.

10 Fig. 3 shows another alternate of the arrangement of Fig. 1 disclosed in the citation 1. In the drawing, the same reference numerals as those in Fig. 1 denote the same parts as those in Fig. 1. A difference between the arrangement of Fig. 3 and that of Fig. 1 is that the recess 15 202 in Fig. 1 is replaced by an overhanging member 206 which is provided only for at least one of the pair of inner lead wires 201 (In the illustrated example, the overhanging member 206 is provided only one lead wire). There is such a description in the citation that, with such 20 an arrangement, the aforementioned substance can deposit on the flare stem but the amount of substance deposited onto the inner lead wire 201 in the vicinity of the sealing part can be reduced, thus suppressing formation of the aforementioned electric path.

25 One of the related citations is JP-A-6-140000 Publication. The citation discloses an arrangement in which, as shown in Fig. 4, a glass bead 101 is fixedly mounted to a pair of lead wires 102. This enables

reduction of an oxidizing rate of the lead wires and avoidance of an extremely short life of a fluorescent lamp. With such an arrangement, the presence of the glass bead 101 enables reduction of the amount of deposit spattered 5 onto the lead wires 102 and onto an area 110 on the flare stem. However, since the above spattered deposit substance deposits on the glass bead 101, a short-circuiting may disadvantageously take place between the pair of lead wires through the deposit on the glass bead 101. In the drawing, 10 reference numeral 105 denotes a bead mount, numeral 106 denotes a filament coil, 105 denotes a bead mount, 109 denotes an exhaust tube.

One of the related citations is JP-A-3-81950 Publication. The citation describes the aforementioned 15 first operation mode. As an arrangement of overcoming the problem with the first operation mode, an arrangement of Fig. 23 is disclosed therein. Fig. 23 shows an arrangement in the vicinity of a lamp electrode. A button stem 27 is air-tightly joined to an end of a glass bulb 21 by means of 20 an adhesive agent (not shown). Provided to the button stem 27 is a support rod 29, on which a heat shielding plate 30 is mounted. The heat shielding plate 30, which is disposed between an electrode 26 and stem 27, is made of heat- resistive metal such as stainless material. The heat 25 shielding plate 30, which is shaped into a trough, covers a rear side of the electrode 26. Numerals 28a and 28b denote lead wires respectively. Such a description is disclosed in the citation that, with such an arrangement, even if the

above first operation mode phenomenon takes place, the possibility of over-heat damage of the button stem 27 can be reduced because of the heat shield.

One of the related citations is JP-A-54-44372

5 Publication. The citation is directed to an improvement in an interior 2 of a fluorescent lamp 1, in which, as shown in Fig. 24, a circular heat shielding plate 13 is provided between a filament 12 and a base 9 to use the base 9 as a coolest point and to prevent heat radiated from the
10 filament 12 from transmitting to the base 9. In this case, reference numeral 14 denotes lead wires, and numeral 15 denotes supporting members for supporting the heat shielding plate 13. This arrangement is intended to avoid deterioration of its good-looking lamp as a product caused
15 by blackening of phosphor coated on a glass tube in the vicinity of the filament. To this end, the base 9 is set to have the coolest point to thereby suppress such blackening. With this arrangement, the shield is provided between the lead wire 14 and a stem 16, which is expected to
20 suppress deposition of the above spattered substance onto the stem 16. However, this arrangement has a problem that, since the heat shielding plate 13 is fixed to the lead wire 14 without any substantial gap therebetween, the above spattered substance deposits on the heat shielding plate,
25 thus disabling prevention of short-circuiting between the pair of lead wires 14.

SUMMARY OF THE INVENTION

The inventors of the present application have examined the fluorescent lamp disclosed in the above citation fluorescent lamp 1 and found several problems that 5 the lamp cannot exhibit sufficient effects of reducing generation of the above first and second operation modes and cannot be easily manufactured on a mass production basis, etc.

(Problem with the First Operation Mode)

10 A problem common to the arrangements of Figs. 1 to 3 is that no consideration is paid to avoiding the first operation mode in these arrangements. The first operation mode takes place for either one of the pair of lead wires, but in these arrangements, it is not clear that the first 15 operation mode occurs in which lead wire. In order to properly cope with the first operation mode, it is necessary, even if the first operation mode takes place for either lead wire, to arrange the lamp in such a manner as to be able to cope with it. However, the citation fluorescent 20 lamp 1 refers only to the fact that the recess, insulation tube and overhanging member are provided only for at least one of the lead wires in pair and fails to refer to the fact that they should be provided for both of the lead wires as its indispensable conditions. Such an 25 arrangement cannot sufficiently cope with the first operation mode.

(Problems with the Second Operation Mode)

(1) With the arrangement of Fig. 1, since the creep-

ing distance of the electric path is longer than that in the prior art, the probability of short-circuit occurrence is reduced to some extent.

5

However, it is not necessarily sufficient and the electric path is established and short-circuited at a certain frequency. That is, as a result of examinations by the present inventors, it has been found that the second operation mode sometimes takes place.

10

(2) With the arrangement of Fig. 3, further, the overhanging member 206 is provided to the inner lead wire 201, which however is basically of a cantilever beam structure. Thus, as will be seen from Fig. 3, the substance deposits on the flare stem by going from the surrounding of the overhanging member, and the amount of such deposit becomes unnegligible. In other words, there cannot avoid eventual establishment of an electric path between the pair of lead wires.

15

20 (Other Problems)

25

(1) The arrangement of Fig. 2, there is described in the citation 1 that the insulation tube 205 may be made of ceramic, quartz or ordinary glass. In the case of using ceramic, however, the material of the flare stem is glass and thus a difference in thermal expansion coefficient between the ceramic and glass becomes large. Such a manufacturing step is employed that the lead wires are

inserted into insulation tubes and then sealed with the flare stem of the glass material. In this case, because of the large difference in thermal expansion coefficient between the both materials, after the flare stem has sealed the insulation tubes, spontaneous cooling thereof involves a problem that the flare stem of glass is cracked. Further, when the insulation tube is made of glass, another problem is that the arrangement cannot sufficiently cope with the first operation mode. This is because generation of the first operation mode causes the lead wires to be heated, which disadvantageously melts the insulation tubes. In addition, even employment of any of the above materials inevitably involves complicated manufacturing steps.

(2) With the arrangement of Fig. 3, there is a description in the citation 1 that the overhanging member 206 may be made of ceramic, quartz, ordinary glass or metal. This arrangement requires the overhanging member 206 to be properly fixed to the lead wire. Otherwise, the overhanging member will be rotated about the lead wire and further moved along the lead wire, thus leading to deterioration of the original function of the member. In order to fix the both, further, some stoppers are necessary. The necessary number of such stoppers is 2 or 4.

When the member is provided to one of the lead wires in pair, the total number of such stoppers is 2 because the electrode is provided at each of both ends of the discharge lamp. When the overhanging member is provided to each of the lead wires in pair, the number of such stoppers is 4 that is twice the above case. This involves a problem that member mounting works become troublesome and its manufacturing steps become complicated. An additional problem is that, when the overhanging member is made of glass material, the lamp cannot sufficiently cope with the first operation mode. This is because occurrence of the first operation mode causes heating of the lead wires to melt the member, with the result that the member eventually drops off from the wires.

It is therefore an object of the present invention to provide a fluorescent lamp which can overcome the above problems in the prior art, and also to provide a method for manufacturing the lamp.

The above object is attained by providing a fluorescent lamp employing any one of two first and second arrangements (1) and (2) which follow.

25 (1) First Arrangement:

In a fluorescent lamp wherein a light emitting envelope is air-tightly sealed at each end with glass sealing material including a glass stem and a pair of first and

second metallic lead wires, and a filament is provided to one ends of the pair of inner lead wires located inside the envelope; an insulator is provided between the filament and a top of the stem so that the first and second inner lead wires are passed through the stem and insulator, and the insulator covers boundary areas on the stem corresponding to the both lead wires or covers the entire top of the stem. In this case, the insulator is provided therein with first and second holes, into which the above lead wires in pair are inserted. A cross-sectional area of the holes is set to be larger than a cross-sectional area of the first and second lead wires. A value obtained by dividing the hole sectional area by the sectional area of the first and second lead wires is set to be not smaller than 1.2 and not larger than 10. Or a value obtained by dividing the diameter of the holes by the diameter of the first and second lead wires may be set to be not smaller than 1.1 and not larger than 3.3.

20 In this arrangement, there also be provided a
fluorescent lamp which comprises a stem having the
first and second lead wires for energization of an
electrode and an electrically-insulating member
provided therein with first and second holes, and
25 wherein the first and second lead wires are inserted in
the first and second holes so that a gap is defined
between a boundary part of the first hole and the first
lead wire in the vicinity of a contact part of the

first hole with the first lead wire.

(2) Second Arrangement:

In a fluorescent lamp which comprises a stem provided with first and second lead wires for energization of an electrode and electrically-insulating first and second members of a tubular shape having the first and second lead wires inserted therein, and wherein a cross-sectional area of the hollow part of the first and second members is larger than a cross-sectional area of the first and second lead wires. In this connection, a value obtained by dividing the cross-sectional area of the hollow part of the first and second members by the cross-sectional area of the first and second lead wires is set to be not smaller than 1.2 and not larger than 10. A value obtained by dividing a diameter of the hollow part of the first and second members by a diameter of the first and second lead wires may be set to be not smaller than 1.1 and not larger than 3.3.

In the first arrangement, since insulator is provided around the first and second lead wires, even when the first operation mode took place, advancement of abnormal discharge can be suppressed. Our experiments have showed that, when the first operation mode took place in a fluorescent lamp not having such an insulator, discharge causes lead wires to melt down to a flare stem level; whereas, when the first operation mode took place in a fluorescent lamp having such an insulator, the provision of the insulator enables such discharge to be suppressed or

stopped. More specifically, it has been confirmed that the discharge was stopped with the lead wires remained on their filament side of the insulator.

With the arrangement, further, since the

5 insulator is provided so as to cover the sealing boundary areas of the glass stem with the lead wires or to cover the entire head area of the stem, spattering of substance from the filament onto the flare stem or sealing areas can be more sufficiently suppressed than the prior art and thus a
10 probability of generating the second operation mode can be reduced. Furthermore, since the insulator is provided therein with first and second holes or is structured as mentioned above, even the substance deposits on the insulator, the deposit will not lead to formation of a
15 short-circuited path between the pair of lead wires. This is because gaps defined between the holes and lead wires act to block the formation of the short-circuited path.

Even in the second arrangement, since the first and second members are provided around the first and second
20 lead wires, even when the first operation mode took place in either lead wire, the advancement of abnormal discharge can be suppressed. When the size of the hollow part of these members is selected sufficiently large when compared with the size or diameter of the lead wires, it has been
25 confirmed that the provision of these members makes it difficult to maintain the above abnormal discharge. It has also been confirmed that, even when the discharge advances from the tip ends of the lead wires toward the flare stem,

the provision of the members makes it difficult to maintain the discharge and the discharge stops short of reaching the members. It has also been confirmed that the absence of such members exhibits no such effect.

5 Further, since these tubular members cover the
sealing areas and have an inner diameter sufficiently large
when compared with the diameter of the lead wires,
formation of a short-circuited path between the lead wires
can be blocked.

10 The second arrangement is featured in that the
first and second members having the hollow part suffi-
ciently larger than the cross-sectional area of the lead
wires are employed by design. This enables sufficient
reduction of a short-circuit probability between the lead
15 wires. Even with the arrangement of Fig. 2, it seems (not
disclosed) that the inner diameter of the tube is slightly
larger than the diameter of the lead wires, but a differ-
ence therebetween is such small as enough to tightly fit
the both.

20 BRIEF DESCRIPTION OF THE DRAWINGS

Figs. 1A to 1C show a flare stem and its vicinity of a prior art fluorescent lamp, with the flare stem having a recess formed therein;

Figs. 2A to 2C show a flare stem and its vicinity
25 of another prior art fluorescent lamp, with the flare stem
having lead wires inserted into insulation tubes;

Figs. 3A to 3C show a flare stem and its vicinity

of a further prior art fluorescent lamp, with the flare stem having an overhanging member provided to one lead wire;

Fig. 4 shows a part of yet a further fluorescent lamp of a structure having lead wires bundled with a glass rod;

Figs. 5A to 5C show a fluorescent lamp in accordance with a first embodiment of the present invention, in which lead wires are inserted into a ceramic plate and held therein;

Fig. 6 shows an entire fluorescent lamp having a stem in Fig. 5 in the first embodiment of the present invention;

Figs. 7A and 7B show the ceramic plate used in the arrangement of Fig. 5 in the first embodiment of the present invention;

Fig. 8 is a perspective view of a flare stem part having a pair of lead wires inserted into the ceramic plate in the first embodiment of the present invention;

Fig. 9 shows steps of manufacturing the fluorescent lamp shown in Fig. 6 in the first embodiment of the present invention;

Figs. 10A to 10C show another method for fixing a ceramic plate by inserting lead wires and an intermediate lead wire into the ceramic plate and bending the intermediate lead wire in the first embodiment of the present invention;

Fig. 11 is a perspective view of a flare stem

part which has a pair of lead wires inserted into a ceramic plate and which is fixed by the intermediate lead wire, in the first embodiment of the present invention;

Fig. 12 shows steps of manufacturing the flare
5 stem shown in Fig. 11 in the first embodiment of the present invention;

Figs. 13A to 13C show a further method for fixing a ceramic plate by inserting lead wires into the ceramic plate and fixing the lead wires by means of stoppers in the
10 first embodiment of the present invention;

Fig. 14 is a perspective view of a flare stem part provided with the ceramic plate having the pair of lead wires inserted thereinto and fixed by the stoppers in the first embodiment of the present invention;

15 Fig. 15 shows steps of manufacturing the flare stem in Fig. 14 in the first embodiment of the present invention;

Figs. 16A and 16B show a perspective view of an insulation tube and 3 views thereof as viewed from its 3
20 sides in a second embodiment of the present invention;

Fig. 17 is a perspective view of a flare stem having the insulation tubes of Fig. 16 in the second embodiment of the present invention;

Figs. 18A to 18C show a view for fixing lead
25 wires by inserting the lead wires into insulation tubes and holding the tubes by means of stoppers in the second embodiment of the present invention;

Fig. 19 shows steps of manufacturing the flare

stem of Fig. 17 in the second embodiment of the present invention;

Figs. 20A and 20B are diagrams for explaining a gap dimension between a top of the flare stem and an 5 insulator provided to the lead wires in the second embodiment of the present invention;

Fig. 21 is an exemplary lighting circuit of a prior art fluorescent lamp;

Fig. 22 shows an appearance of a fluorescent lamp 10 device corresponding to a combination of a fluorescent lamp and a lighting fixture;

Figs. 23A, 23B and 24 show a structure of an electrode part and its vicinity of a prior art fluorescent lamp; and

15 Fig. 25 shows a structure of an electrode part and its vicinity of a lamp in accordance with a third embodiment of the present invention.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Embodiments of the present invention will be 20 explained with reference to the accompanying drawings.

(Embodiment 1)

Fig. 5A shows a cross-sectional view of one of ends (having stems for holding respective electrodes) of a fluorescent lamp in accordance with a first embodiment of 25 the present invention, Fig. 5B shows a cross-sectional view of the same taken along line A-A in Fig. 5A, and Fig. 5C shows a cross-sectional view of the same taken along line

B-B in Fig. 5A. Fig. 6 is a perspective view of an entire straight fluorescent lamp having such an electrode structure as shown in Fig. 5 in the present embodiment. In the drawing, a light emitting envelope 1 as a glass tube is
5 formed on its inside wall with a phosphor film. The light emitting envelope 1 is closed at its ends by respective flare stems 2 so that the interior of the envelope is sealed against outside the envelope. Passed through the flare stem 2 air-tightly are a pair of inner lead wires 3a
10 and 3b each made of a nickel coated iron wire having a diameter of 0.6mm. The inner lead wires 3a and 3b are provided at their one ends with a filament 4 made of tungsten. Coated on the filament 4 is emitter substance such as barium oxide.

15 Provided to the flare stem 2 is an insulator (ceramic plate in this illustrated example) 5 which is formed therein with two holes of 1mm in diameter so as to cover an area of the stem between sealed parts of the pair of inner lead wires 3a and 3b. The insulator 5 is loosely
20 mounted on the stem so that, as the insulator goes toward the filament, a distance between the lead wires becomes larger.

 The insulator 5 as a ceramic plate was made to have a nearly rectangular shape having a vertical dimension
25 of 7mm, a horizontal dimension of 14mm and a thickness of 1mm, and made of alumina ceramic. Fig. 7A is a perspective view of the ceramic plate, and Fig. 7B shows views as viewed from 3 sides of the plate. Fig. 8 shows a

perspective view of a flare stem part having the pair of lead wires inserted into the ceramic plate.

Fig. 9 shows steps of manufacturing a fluorescent lamp using the ceramic plate. As shown in Fig. 9(a), a 5 stem 1 has a pair of inner lead wires 2a and 2b. The pair of inner lead wires 2a and 2b are made substantially straight and passed through a ceramic or insulating plate 3 (refer to Fig. 9(a)). After passed through the insulating plate, the pair of intermediate lead wires are bent (refer 10 to Fig. 9(c) and 9(d)). This bending enables limitation of the movement of the ceramic plate along the intermediate lead wires. Then an electrode (filament) 4 is fixed to the lead wires (refer to Fig. 9(e)), thus forming a stem mount 5. The stem mounts 5 prepared in this way are sealed 15 inside a glass envelope 6 at both ends thereof, the envelope being coated on its inside wall with phosphor (refer to Fig. 9(f)). At this time, the glass envelope is provided at its one end with an exhaust tube for discharging air inside the glass envelope. At the same time when 20 the glass tube is vacuumed through the exhaust tube, a current is supplied to the electrode to activate carbonate such as barium carbonate coated on the electrode, a suitable amount of inactive gas is sealingly charged into the tube, a suitable amount of mercury is charged there- 25 into, and then the exhaust tube is cut and sealingly closed to thereby complete a fluorescent lamp (refer to Fig. 9(g)).

The lamp having such a structure was lighted as

combined with a high frequency lighting ballast (high frequency lighting circuit) to confirm failure modes (that is, the aforementioned first and second operation modes) of the lamp at the end of its life. The confirmation was

5 conducted through tests by coating the same amount of coat as its mass-production design value on one of the lamp electrodes and coating an excessively small amount of emitter substance on the other electrode to shorten a life end reproduction time. Further, for the purpose of

10 observing the vicinities of the electrodes, such a glass envelope 6 was employed that the phosphor film on the inside wall of the envelope is not formed near the electrodes.

Our experiments have showed that, even when the

15 filament was broken, discharge was maintained and further that, even when the inner lead wires were changed to an electrode (hot spot) and started melting, the melting stopped at the position of the insulator and did not reach such a situation that the stem glass melted. This means

20 that the first operation mode took place but it was able to be stopped. Further, it has also been observed that substance spattered from the filament was adhered and deposited on the insulator, but it has been confirmed that supply of a current to the lead wires did not lead to a

25 stem melt mode. This means that the ceramic plate performed a function of blocking the second operation mode.

For reconfirmation, a prior art fluorescent lamp having substance already spattered from filaments and

deposited on the tops of the stems at the end of its life was subjected to measurement of a resistance between the pair of lead wires. The resistance was as very small as 50 to 200Ω.

5 The lamp of the present embodiment, on the other hand, was subjected to similar measurement of a resistance. The resistance was substantially infinity. Thus it has been confirmed that the embodiment lamp can exhibit a sufficient effect of preventing the second operation mode.

10 This is considered to be because the insulator is mounted as not fully fixed to the lead wires but as moved somewhat, so that the ceramic plate is partially contacted with the lead wires, that is, in a point contact relationship therebetween. For this reason, it is considered that

15 establishment of an electric path is blocked. In other words, it can be considered that a gap between the ceramic plate and lead wires contributes to avoidance of the establishment of the electric path. On the contrary, when the ceramic plate is fully fixed to the lead wires, this

20 may result in that an electric path is highly possibly established between the pair of lead wires.

Although the insulator has been made of alumina ceramic in the present embodiment, it can be made of, in addition to it, any material such as forsterite ($2\text{MgO} \cdot \text{SiO}_2$), steatite ($\text{MgO} \cdot \text{SiO}_2$) or jircon ($\text{ZrO}_2 \cdot \text{SiO}_2$), so long as it is insulating ceramic. The insulator further may be made of heat-resistive glass such as quartz glass or hard glass or made of mica. In other words, the insulator may

be made of any material so long as it is highly resistive to heat, stable, produces no impurity gas in vacuum, and more preferably, if it is excellent in processability.

Although the diameter of the wire hole has been 5 made to be 1mm in the present embodiment, the cross-sectional area of the hole is basically required to be only larger than the cross-sectional area of the inner lead wire. When consideration is paid even to needs of mountability of the wires to the stem on a mass production 10 basis, avoidance of too large play of the insulator after the lamp bulb is completed, and avoidance of generation of a little strange sound resulting from the too large play, however, the sectional area of the hole is preferably in a range of 1.2 to 10 times the sectional area of the inner 15 lead wire. When the hole and lead wire are both circular in their cross-sectional shape, a ratio between the wire and hole in the cross-sectional area is preferably 1.1 to 3.3 (which holds true for cases which follow). When the ratio is smaller than the above value, the mountability 20 becomes worse. When the ratio is larger than the above value, the ceramic plate produces a little strange sound, disadvantageously degrading its product value. Further, when the cross-sectional area of the hole becomes too 25 large, it is impossible to sufficiently block deposition of substance spattered to the vicinity of the lead wires, thus disabling sufficient suppression of the second operation mode.

In this connection, a pitch between the two holes

may be set to be nearly equal to a pitch between the lead wires. Though the hole shape has been made circular in the present embodiment, it goes without saying that any other shape may be employed with substantially the same effects

5 as in the above case.

Further, although the shape of the insulator has been made rectangular in the present embodiment, any shape may be employed so long as it can cover the entire head part of the stem. For example, the insulator shape may be

10 made not plate-like but simply block-like.

Explanation will then be made as to a spacing between the insulator provided to the lead wires and the flare stem. Figs. 20A and 20B are diagrams for explaining the spacing. In Fig. 20A, a spacing 502 between a top 501 of the flare stem 2 upwardly projected and the insulator 5 provided to lead wires 3a and 3b is set to be desirably not smaller than 0mm and not larger than 5mm. As shown in Fig. 20B, the spacing 502 between the top 501 of the flare stem 2 upwardly recessed and the insulator 5 provided to the lead wires 3a and 3b is set to be desirably not smaller than 0mm and not larger than 5mm. The flare stem can have one of various sorts of shapes but the top of the flare stem and the insulator should be set to be desirably not smaller than 0mm and not larger than 5mm. In this case,

20 the spacing of 0mm means that the top 501 of the flare stem 2 comes into contact with the insulator 5 provided to the lead wires 3a and 3b.

25

Shown in Fig. 10 is another method for fixing the

insulator 5 in the present embodiment. In the drawing, the insulator 5 is provided therein with three holes which have a cross sectional area of 1.2 to 10 times as large as the cross-sectional area of the pair of inner lead wires 3a and

5 3b.

Inserted into these holes and passed therethrough are the inner lead wires 3a and 3b as well as an intermediate lead wire 6 in the stem between the pair of intermediate lead wires. Further, the intermediate lead 10 wire 6 is bent to thereby hold the insulator 5. Fig. 11 shows its perspective view.

In this fixing method, even when the first operation mode takes place and the lead wires 3a and 3b melted and detached, the insulator is still fixed by means 15 of the intermediate lead wire 6, thus avoiding the detachment of the insulator. Therefore, even when the lead wires 3a and 3b are detached, generation of the second operation mode can be suppressed.

Fig. 12 shows steps of manufacturing a fluorescent lamp having such a structure as mentioned above. Figs. 12(a) to 12(f) correspond to Figs. 9(a) to 9(f). The steps of Fig. 12 are substantially the same as those of Fig. 9, except that a step is newly added for inserting the intermediate lead wire 6 into the associated hole and 25 bending the wire.

Figs. 13A to 13C show a further method for fixing the insulator 5 in the present embodiment. As shown in Fig. 13B, the insulator 5 is provided therein with two

holes which have a sectional area of 1.2 to 10 times as large as the sectional area of the pair of inner lead wires 3a and 3b. The pair of inner lead wires 3a and 3b are inserted into the two holes and the insulator 5 is held by 5 stoppers 7a and 7b provided at halfway of the inner lead wires 3a and 3b. The stoppers 7a and 7b are each made of a metal wire and fixed to the lead wires by welding.

Although the metal wires have been used as the stoppers by welding in this example, any material other 10 than the metal wires can be employed without any limitation, so long as it can restrict the movement of the insulator.

Fig. 14 is a perspective view of a flare stem part of the lamp shown in Fig. 13.

15 Although the explanation has been made in connection with the flare stem as sealing member which is most commonly used in the fluorescent lamp in the embodiment of the present invention, another sealing member using glass such as a button stem or a pinch seal may be employed 20 to provide substantially the same effects as the above.

Fig. 15 shows steps of manufacturing a fluorescent lamp having such a structure as mentioned above, in which Fig. 15(a) to 15(e) correspond to Figs. 9(a) to 9(e). The steps of Figs. 15(a) to 15(e) are substantially the 25 same as those of Figs. 9(a) to 9(f), except that a step of fixing the stoppers is newly added.

(Embodiment 2)

Figs. 16 to 19 are diagrams for explaining a

second embodiment of the present invention.

In the present embodiment, in place of the insulator such as the ceramic plate, a tubular electrical insulator (which will also be sometimes referred to as the 5 insulation tube, hereinafter) is used. Fig. 16A is a perspective view of the insulation tube, and Fig. 16B shows three views as viewed from three sides thereof. In the present embodiment, each of the lead wires is inserted into each of the insulation tubes, which in turn are fixed by 10 means of respective stoppers. Fig. 17 shows its perspective view, and Fig. 18 shows three views of a fluorescent lamp having the stem of Fig. 17. Fig. 18A shows a cross-sectional view of an end (including the step for holding the electrode) of the fluorescent lamp, Fig. 18B is a 15 cross-sectional view thereof taken along line A-A in Fig. 18A, and Fig. 18C is a cross-sectional view thereof taken along line B-B in Fig. 18A.

As shown in Fig. 17, a filament 4 is provided at one ends of a pair of lead wires 3a and 3b having a 20 diameter of 0.6mm provided in the flare stem 2. The filament 4 is coated with emitter substance such as barium oxide.

Mounted in and on the flare stem 2 are the pair of inner lead wires 3a and 3b as well as insulators 5a and 25 5b covering respective interface sealing parts of the stem with the lead wires. In the illustrated example, the insulator was made in the form of a hollow cylinder having an inner diameter of 1mm, an outer diameter of 4mm and a

height of 7mm. These insulators 5a and 5b are loosely mounted by means of the stoppers 7a and 7b made of nickel wires at halfway of the respective lead wires.

Fig. 19 shows steps of manufacturing a fluorescent lamp having such a structure as mentioned above. Figs. 19(a) to 19(e) correspond to Figs. 9(a) to 9(e). The steps of Figs. 19(a) to 19(e) are substantially the same as those of Figs. 9(a) to 9(f), except that the fixing step is replaced by a step of inserting the insulation tubes and 10 fixing the tubes by respective stoppers.

When the lamp having such a structure as mentioned above is combined with the high frequency lighting ballast (high frequency lighting circuit) explained in the first embodiment and then lighted to confirm the life 15 end failure mode, it has been confirmed that the stem will not melt even in either mode of the first and second operation modes.

In the first mode, after the filament was broken, discharge was maintained with one lead wire, the lead wire 20 was melted, and the discharge stopped when the melting of the lead wire reached the insulator, without stem melting.

Since the insulators function to prevent the substance spattered from the electrode from being adhered to or deposited on the interface sealing parts of the stem 25 with the pair of lead wires, the second operation mode did not take place. As a result of measuring a resistance between the both lead wires, it has been confirmed that the resistance was substantially infinity.

In this system, however, in the case where the hollow part is too large in diameter when compared with the diameter of the lead wire, it is considered that, when the lead wire was melted, the stopper may also be melted,

5 whereby the insulator may be dismounted. To avoid this, the sectional area of the hollow is optimumly in a range of 1.2 to 4 times the sectional area of the lead wire, and preferably in a range of 1.2 to 10 times.

Although the insulator has been made cylindrical
10 in the present embodiment, any other ceramic plate 3-dimensional shape may be employed so long as it can cover the interface sealing parts of the stem with the lead wires.

(Embodiment 3)

15 A third embodiment of the present invention can be suitably applied to a discharge lamp including a glass envelope having an outer diameter of not smaller than 13mm and not larger than 29mm. The envelope has a wall thickness of about 0.6mm to 0.7mm.

20 The above will be explained in connection with Fig. 25. A glass envelope 1 is coated on its inner wall with phosphor 4. An electrode 9 is fixedly mounted to a pair of lead wires 8. The glass envelope has an outer diameter D and an inner diameter d. The size of a stem 7
25 and the magnitude of a spacing d_s between the lead wires at the tip end of the stem depend on the magnitude of the inner diameter of the glass envelope. The inventors of the present application have found that, when the spacing d_s

between the lead wires is in a certain range, generation of the second operation mode can be avoided. When the spacing is narrowed to some extent, the creeping distance on the stem between the lead wires in pair becomes short. This

5 tends to cause a short-circuiting, thus generating the second operation mode. It has been found that lamps using glass envelopes having outer diameters of not smaller than 5mm and not larger than 33mm and using stems with lead wires tend to easily cause the second operation mode.

10 Thus, in the case of such lamps, it is especially preferable to provide such a member as shown in Fig. 7 or Fig. 16 between the electrode and stem, though not illustrated in Fig. 25.

(Embodiment 4)

15 The lamp having such a structure as shown in Embodiments 1 to 3, when combined with a known fluorescent lamp lighting circuit, can form a fluorescent lamp device.

An example of the fluorescent lamp lighting circuit is shown in Fig. 21. In the drawing, reference 20 numeral 1 denotes an A.C. power source, numeral 2 denotes a rectifier circuit, 3 denotes a smoothing circuit, 4 denotes a high frequency inverter lighting circuit, and 5 denotes a fluorescent lamp.

Fig. 22 shows an appearance of a fluorescent lamp 25 device comprising a combination of the fluorescent lamp 1 in accordance with the embodiment of the present invention and a lighting fixture 2 incorporating such a lighting circuit as shown in Fig. 21.

As has been explained in the foregoing, in accordance with the foregoing embodiments of the present invention, the earlier-mentioned problems can be suppressed or minimized.
